

Setting Up the System

- **sudo yum update -y**

This command refreshes the computer's internal list of software and updates everything to the newest version. It ensures the system is secure and ready for new apps.

- **sudo yum install -y python3 python3-pip git**

This installs the three main tools you need: **Python** (the engine that runs the code), **Pip** (the tool that downloads extra features for the engine), and **Git** (the tool that fetches code from the internet).

Managing the Files

- **git clone (GITHUB_REPO_URL)**

This reaches out to GitHub and pulls a copy of your project code onto your current computer, placing it inside a folder named `project_code`.

- **cd (project directory name)**

This stands for "change directory." It moves you inside the project folder so you can start working on the files you just downloaded.

- **ls**

This is short for "list." It shows you all the files and folders in your current spot, similar to looking at a list of files in a window on your desktop.

- **cd ..**

This moves you backward one step, out of the current folder and into the "parent" folder that contains it.

Editing and Preparing

- **nano**

This opens a very simple, "no-frills" text editor inside the terminal. It's used for quickly typing notes or changing settings in a file without needing a mouse.

- **pip3 install -r requirements.txt**

Most projects need specific "plugins" or extra parts to work. This command reads a `requirements.txt` and automatically downloads every extra part the project needs.

Running the Program

- **python3 (python file name)**

This is the "Start" button. It tells the Python engine to read your specific file and run the application.

Pull Change from GitHub Repo

- `git pull origin main`
